

Import Data using Transform Map

1. Brainstorming & Ideation Phase

The project is based on improving the process of importing external data into ServiceNow. The existing process may involve manual data entry, inconsistent field values, and errors when data from an external source needs to be added to ServiceNow. The project idea was developed to reduce manual effort and provide a more efficient way to import and organize data.

The main idea is to use ServiceNow Import Sets and a Transform Map to transfer data from an imported source into the appropriate target table. The Transform Map defines how source fields are mapped to target fields and helps transform the imported information into the required format.

The project user story is: As a ServiceNow user, I want to import external data using a Transform Map so that records are automatically mapped and loaded into the correct target table with minimal manual intervention.

The proposed solution focuses on creating a simple and reliable data-import process. It helps reduce manual data entry, minimize mapping errors, maintain consistent data, and improve the efficiency of data management in ServiceNow.
