

Import Data Using Transform Map

5. Project Development Phase

The development phase implements the planned data import process in ServiceNow. The main development component is a Transform Map, which is used to transfer data from an imported data set into the required target table.

A data source is first created and the required file containing the source records is imported into ServiceNow. The imported data is loaded into an Import Set table, which temporarily stores the source records before transformation.

A Transform Map is then created to define the relationship between the Import Set table and the target ServiceNow table. The source fields are mapped to the corresponding target fields so that the imported values are placed in the correct columns.

The required field mappings are configured according to the structure of the source data. An appropriate coalesce field can be selected when existing records need to be identified and updated instead of creating duplicate records.

After configuring the Transform Map, the import process is tested by running the transform. The Import Set and Transform History are checked to verify that records are successfully transformed and that any errors can be identified and corrected.

This development implementation provides a controlled connection between external source data and the ServiceNow target table, making data migration faster, more consistent, and easier to manage.

Development Steps

- Create and configure the required Data Source.
- Upload the source data file into ServiceNow.
- Load the file into the Import Set table.
- Create a Transform Map for the target table.
- Map source fields to the corresponding target fields.
- Configure coalesce when required to avoid duplicate records.
- Run the Transform and review the transformation results.
- Verify the imported records in the target table.
