

Import Data Using Transform Map

4. Import Data Using Transform Map

The Import Data process in ServiceNow is used to bring data from an external source into a ServiceNow table. A Transform Map defines how the imported source data is mapped and transformed into the target table.

The first activity is to prepare the source data, such as a CSV or Excel file, with the required field names and values. In ServiceNow, the data can then be loaded into an Import Set.

The next activity is to create a Transform Map. The Transform Map connects the Import Set fields with fields in the target ServiceNow table. Field Maps are created to specify which source field should be placed into each target field.

The transform process is then executed to move the imported data from the Import Set into the target table. During transformation, ServiceNow applies the configured field mappings and transformation logic.

The final activity is to verify the transformed records in the target table. The imported values, field mappings, and any transformation results should be checked to confirm that the data has been transferred correctly.
